# 1. Cochain Complexes and Cohomology

### 1.1. Cochain Complexes

**Definition 1.** A **cochain complex** is a sequence of vector spaces  $\{C^k\}_{k\in\mathbb{Z}}$  together with a sequence of linear maps  $d_k: C^k \to C^{k+1}$  s.t.  $d_{k+1} \circ d_k = 0$  (i.e. im  $d_k \subseteq \ker d_{k+1}$ ) for every  $k \in \mathbb{Z}$ . The subscript for d will often be dropped and we call d the **differential** or **boundary operator** of the cochain complex.

**Example 1.** For a smooth manifold M, the sequence of vector spaces given by  $C^k = \Omega^k(M)$  and with  $d_k : \Omega^k(M) \to \Omega^{k+1}(M)$  being the exterior derivative, is a cochain complex.

**Definition 2.** (i) A sequence of linear maps

$$A \xrightarrow{f} B \xrightarrow{g} C \tag{1}$$

is said to be **exact at** B if im  $f = \ker g$ .

(ii) A sequence of linear maps

$$A^0 \xrightarrow{f_0} A^1 \xrightarrow{f_1} A^2 \xrightarrow{f_2} \dots \xrightarrow{f_{n-1}} A^n$$
 (2)

is said to be **exact** if it is exact at every  $A^k$  for  $k \neq 0, n$ .

(iii) A sequence of five linear maps of the form

$$0 \to A \xrightarrow{f} B \xrightarrow{g} C \to 0 \tag{3}$$

is called a **short exact sequence**.

Remark. (i) For a short exact sequence, as above, f is injective and g is surjective.

- (ii) The sequence  $0 \xrightarrow{f} B \xrightarrow{g} C$  is exact if and only if g is injective.
- (iii) The sequence  $A \xrightarrow{f} B \xrightarrow{g} 0$  is exact if and only if f is surjective.

### 1.2. Cohomology of a Cochain Complex

Element in	are generally called	and in deRham cohomology called
$C^k$	k-cochains	k-form
$\ker d_k$	k-cocycle	closed $k$ -form
$\operatorname{im} d_{k-1}$	k-coboundary	exact $k$ -form

**Definition 3.** Let  $\mathcal{C} := (\{C^k\}_{k \in \mathbb{Z}}, \{d_k\}_{k \in \mathbb{Z}})$  be a cochain complex. Then the quotient vector space

$$H^{k}(\mathcal{C}) := \underbrace{\ker d_{k}}_{=:Z^{k}(\mathcal{C})} / \underbrace{\operatorname{im} d_{k-1}}_{=:B^{k}(\mathcal{C})}$$
(4)

is called the k-th cohomology vector space of  $\mathcal{C}$ . The equivalence class  $[c] \in H^k(\mathcal{C})$  of a cocycle  $c \in \ker d_k$  is called its cohomology class.

*Remark.* The cohomology  $H^k$  of a cochain complex is a measure for the failure of  $\mathcal{C}$  to be exact at  $C^k$ .

**Definition 4.** Let  $\mathcal{A}, \mathcal{B}$  be two cochain complexes with differentials d, d'. A **cochain map** is a sequence  $\{\varphi_k\}_{k\in\mathbb{Z}}$  of linear maps  $\varphi_k: A^k \to B^k$  s.t.  $d'_k \circ \varphi_k = \varphi_{k+1} \circ d_k$  for every  $k \in \mathbb{Z}$ . As with the differential, we will drop the subscript of  $\varphi$  when it is clear from the context.

Remark. A cochain map  $\varphi$  induces a well-defined linear map  $\varphi: H^k(\mathcal{A}) \to H^k(\mathcal{B})$  between the cohomology vector spaces of  $\mathcal{A}$  and  $\mathcal{B}$  via  $\varphi[a] = [\varphi(a)]$ . To see this, let  $[a] \in H^k(\mathcal{A})$  i.e. let  $a \in \ker d_k$ . Then

$$d'_k(\varphi_k(a)) = \varphi_{k+1}(d_k(a)) = \varphi_{k+1}(0) = 0$$
(5)

Hence  $\varphi_k$ :  $\ker d_k \to \ker d'_k$ . To show that it is well-defined, let [a] = 0 in  $H^k(\mathcal{A})$ . Then  $a \in \operatorname{im} d_{k-1}$  i.e.  $\exists b \in A^{k-1} : d_{k-1}(b) = a$ . Hence

$$\varphi_k(d_{k-1}(b)) = d'_{k-1}(\varphi_{k-1}(b)) \in \text{im } d'_{k-1}, \tag{6}$$

and thus  $[\varphi(a)] = 0$  in  $H^k(\mathcal{B})$ .

**Example 2.** Let  $F: N \to M$  be a smooth map. Then  $F^*: \Omega^k(M) \to \Omega^k(N)$  commutes with the differential and therefore induces a map on cohomology.

### 1.3. Connecting Homomorphism

**Definition 5.** A sequence of cochain complexes

$$0 \to \mathcal{A} \xrightarrow{i} \mathcal{B} \xrightarrow{j} \mathcal{C} \to 0 \tag{7}$$

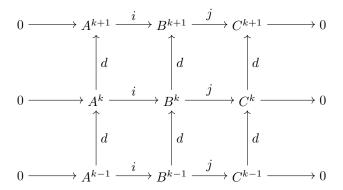

is called **short exact** if i and j are cochain maps and for every  $k \in \mathbb{Z}$  the sequence

$$0 \to A^k \xrightarrow{i} B^k \xrightarrow{j} C^k \to 0 \tag{8}$$

is short exact.

Given the data of a short exact sequence of cochain complexes, one can construct the following linear map  $\delta^*: H^k(\mathcal{C}) \to H^{k+1}(\mathcal{A})$ , called the **connecting homomorphism**. Its purpose will become clear via the zig-zag-Lemma, Lemma ??.

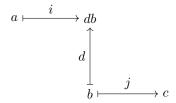

Let  $k \in \mathbb{Z}$  be arbitrary and consider the following diagram:

Now consider the following steps:

- Let [c] be an arbitrary element in  $H^k(\mathcal{C})$ . That is, let  $c \in C^k \cap \ker d$
- Since the middle sequence in the above diagram is exact at  $C^k$ , the map j is surjective and there exists a  $b \in B^k$  s.t. j(b) = c.
- Apply d to b to obtain  $db \in B^{k+1}$ .
- Since j is a chain map and  $c \in \ker d$  we have j(db) = d(j(b)) = d(c) = 0. Hence  $db \in \ker j$  and thus, since the upper sequence is exact at  $B^{k+1}$ , the element db lies in the image of i.
- Hence there exits an element  $a \in A^{k+1}$  s.t. i(a) = db.
- In order to see that  $a \in A^{k+1} \cap \ker d$ , note that i(da) = d(i(a)) = d(db) = 0. Since the upper sequence is exact at  $A^{k+1}$ , the map i is injective and thus da = 0.

We define the connecting homomorphism  $\delta^*: H^k(\mathcal{C}) \to H^{k+1}(\mathcal{A})$  via  $\delta^*[c] = [a]$ . The above is summarized in the following diagram

or as  $\delta^* = i^{-1} \circ d \circ j^{-1}$ , where  $i^{-1}$  and  $j^{-1}$  is to be understood as choosing one element in the pre-image. By tracing through the argument with another  $c' \in C^k \cap \ker d$  as well as c + c', we note that this map is linear. In order to show that it is well defined i.e. that [a] depends neither on the choice of representative

c of [c], nor on the choice of pre-image b, under the map j, of that representative c (note that the choice of pre-image of db was unique since i is injective), we argue as follows:

Let  $c' \in C^k \cap \ker d$  be another representative of [c]. Then we want show that a - a' is a coboundary i.e. that there is a  $z \in A^k$  s.t. a - a' = dz.

- Since c c' represents [0] there is a  $x \in C^{k-1}$  s.t. c c' = dx.
- Since the sequence is exact at  $C^{k-1}$ , the map j is surjective and thus there exists a  $y \in B^{k-1}$  s.t. j(y) = x.
- Note that the element  $u := (b b') dy \in B^k$  lies in ker j since

$$j(dy - (b - b')) = j(dy) - j(b - b') = dx - (c - c') = 0.$$
(9)

- Thus, by exactness at  $B^k$ , there is a  $z \in A^k$  s.t. i(z) = u.
- Finally,

$$i(dz - (a - a')) = d((b - b') - dy)) - i(a - a')) = d(b - b') - i(a - a') = 0 (10)$$

since a - a' was chosen to lie in the *i*-pre-image of d(b - b').

• Thus, by the injectivity of i, we conclude that dz = a - a'.

To show well-definedness with respect to the choice of pre-image of c, let b' be another element in the pre-image of  $c \in C^k$ . Then j(b-b')=c-c=0 and hence there exists a  $u \in A^k$  such that i(u)=b-b'. But now

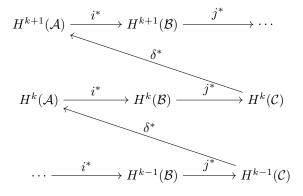

$$i(du) = d(i(u)) = d(b - b').$$
 (11)

Thus, since i is injective du = c - c' and c - c' is a coboundary and  $\delta^*$  does not depend on the choice of pre-image of c.

Theorem 1. (Zig-Zag-Lemma) Let

$$0 \to \mathcal{A} \xrightarrow{i} \mathcal{B} \xrightarrow{j} \mathcal{C} \to 0 \tag{12}$$

be a short exact sequence of cochain complexes. Then the sequence

is long exact.

*Proof.* Let  $k \in \mathbb{Z}$  be arbitrary.

• Exactness at  $H^k(\mathcal{A})$  i.e.  $\operatorname{im} \delta^* = \ker i^*$ " $\subseteq$ ": Let  $\delta^*[c] \in H^k(\mathcal{A})$ . Then as in the construction of  $\delta^*$  a representative of the class  $\delta^*[c]$  is given by the pre-image under i of db. Thus  $i^*\delta^*[c] = [i(\delta^*(c))] = [db] = 0$ .

" $\supseteq$ ": Let  $i^*[a] = 0$ . That is, let i(a) be a coboundary in  $B^k$ . Then there is a  $b \in B^{k-1}$  s.t. i(a) = db. Applying j to this b gives  $j(b) \in C^{k-1}$ . Tracing back the steps in the opposite direction shows that applying  $\delta^*$  to [j(b)] gives [a].

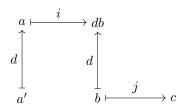

• Exactness at  $H^k(\mathcal{B})$  i.e.  $\lim i^* = \ker j^*$ " $\subseteq$ ": Let  $i^*[a] \in H^k(\mathcal{B})$ . Then  $j^*(i^*[a]) = j^*[i(a)] = [j(i(a))] = [0]$ , since (??) is exact at  $B^k$ .

"\(\textit{?"}:\) Let  $[b] \in \ker j^*$ . Then  $j^*[b] = [j(b)] = 0$ . Hence j(b) = dc for some  $c \in C^{k-1}$ . Since j is surjective, there is a  $b' \in B^{k-1}$  s.t. j(b') = c and thus j(b-db') = j(b) - dj(b') = 0. Hence there is a  $a \in A^k$  s.t. i(a) = b - db'. Thus  $i^*[a] = [i(a)] = [b - db'] = [b]$ , showing that  $[b] \in \operatorname{im} i^*$ .

• Exactness at  $H^k(\mathcal{C})$  i.e. im  $j^* = \ker \delta^*$ " $\subseteq$ ": Let  $[b] \in H^k(\mathcal{B})$ . Then by definition  $\delta^*j^*[b] = \delta^*[j(b)]$ . Now we trace the element [j(b)] through the machinery for  $\delta^*$ :

We may pick b as the pre-image of j(b) in  $B^k$ . Since  $[b] \in H^k(\mathcal{B})$ , the element b is a cocycle and thus db = 0. Hence db = i(0) and thus by the injectivity of i we conclude  $\delta^*[j(b)] = [0]$ .

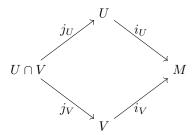

"\(\to\$": Let  $\delta^*[c] = [a] = 0 \in H^k(\mathcal{A})$ . Then a = da' with  $a' \in A^{k-1}$ . On the other hand we may trace back a along the path of  $\delta^*$  to an element  $c \in C^{k-1}$  as

But now b - i(a') is a coboundary since d(b - i(a')) = db - i(da') = 0 and also j(b - i(a')) = j(b) - j(i(a')) = c - 0 = c by the exactness at  $B^{k-1}$ .

### 1.4. Mayer-Vietoris Sequence

Let M be a manifold and let  $\{U, V\}$  be an open cover of M with the following inclusion maps, forming a commutative diagram of manifolds.

For every  $k \in \mathbb{Z}$ , the above maps induce the sequence

$$0 \to \Omega^k(M) \xrightarrow{i} \Omega^k(U) \oplus \Omega^k(V) \xrightarrow{j} \Omega^k(U \cap V) \to 0$$
 (13)

defined via

$$i: \omega \mapsto (i_U^* \omega, i_V^* \omega) = (\omega|_U, \omega|_V), \quad \omega \in \Omega^k(M)$$
 (14)

$$j: (\omega, \sigma) \mapsto j_U^* \omega - j_V^* \sigma = \omega|_{U \cap V} - \sigma|_{U \cap V}, \quad \omega \in \Omega^k(U) \oplus \Omega^k(V).$$
 (15)

We call i the **restriction map** and j the **difference map**. Together with the respective boundary operator d, the three sequences of vector spaces (indexed by k) form cochain complexes; in the case of  $\Omega^k(U) \oplus \Omega^k(V)$  this can be seen by noting that  $\Omega^k(U) \oplus \Omega^k(V) \cong \Omega^k(U \coprod V)$ , where  $\coprod$  denotes the disjoint union, and thus  $d(\omega, \sigma) = (d\omega, d\sigma)$ .

**Proposition 1.** The maps i and j are cochain maps.

*Proof.* Let  $k \in \mathbb{Z}$  be arbitrary. Let  $\omega \in \Omega^k(M)$  be arbitrary. Then

$$d(i(\omega)) = (d(i_U^*(\omega), d(i_V^*(\omega))) = (i_U^*(d\omega), i_V^*(d\omega)) = i(d(\omega)).$$
(16)

Let  $(\omega, \sigma) \in \Omega^k(U) \oplus \Omega^k(V)$  be arbitrary. Then

$$d(j(\omega,\sigma)) = d(j_U^*\omega) - d(j_V^*\sigma) = j_U^*(d\omega) - j_V^*(d\sigma) = j(d(\omega,\sigma)).$$
 (17)

**Proposition 2.** For every  $k \in \mathbb{Z}$ , the sequence

$$0 \to \Omega^k(M) \xrightarrow{i} \Omega^k(U) \oplus \Omega^k(V) \xrightarrow{j} \Omega^k(U \cap V) \to 0$$
 (18)

is short exact.

*Proof.* Exactness at  $\Omega^k(M)$  and  $\Omega^k(U) \oplus \Omega^k(V)$  are clear. For the exactness at  $\Omega^k(U \cap V)$  i.e. for the surjectivity of the difference map j, consider the following<sup>1</sup>:

<sup>&</sup>lt;sup>1</sup>It is generally not true that there exists a smooth extension of  $\omega \in \Omega^k(U \cap V)$  to U or V. So the naive idea of choosing such an extension  $\eta$  and defining  $j^{-1}(\omega) = (\eta, 0)$  does not work.

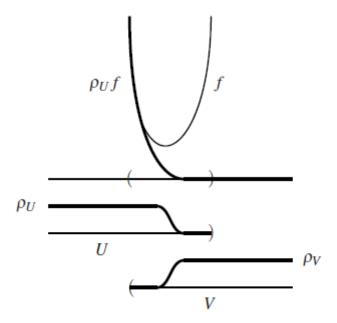

Figure 1: Rewriting a function f on  $U \cap V$  as a difference of functions on U and V. Fig. 26.1 [TuMf].

Let  $\omega \in \Omega^k(U \cap V)$  be arbitrary and let  $\{\rho_U, \rho_V\}$  be a partition of unity subordinate to the open cover  $\{U, V\}$ . Then define the forms

$$\eta_U := \begin{cases} \rho_V \omega, & \text{on } U \cap V \\ 0, & \text{on } U \setminus \text{supp } \rho_V \end{cases}$$
 (19)

and

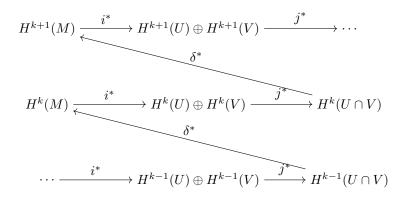

$$\eta_V := \begin{cases} \rho_U \omega, & \text{on } U \cap V \\ 0, & \text{on } V \setminus \text{supp } \rho_U. \end{cases}$$
 (20)

To see that  $\eta_U$  defines a smooth k-form, note that the intersection  $(U \cap V) \cap (U \setminus \text{supp } \rho_V) = (U \cap V) \cap (\text{supp } \rho_V)^c$  is an open set, on which 0 and  $\rho_V \omega$  agree. Hence they can be glues to a smooth form. The same is true for  $\eta_V$ . Now we have

$$j(\eta_U, -\eta_V) = \eta_U|_{U \cap V} + \eta_V|_{U \cap V} = \rho_U \omega + \rho_V \omega = \omega, \tag{21}$$

showing that j is surjective.

Thus, as a result the Zig-Zag-Lemma applies and we obtain a long exact sequence in cohomology, called the Mayer-Vietoris sequence:

Let us see explicitly what the connecting homomorphism does here:

$$\alpha \xrightarrow{i} (d\zeta_U, -d\zeta_V)$$

$$d \downarrow \\ (\zeta_U, -\zeta_V) \xrightarrow{j} \zeta$$

- 1. Let  $\zeta$  be a closed k-1-form in  $U \cap V$  and let  $\{\rho_U, \rho_V\}$  be a partition of unity subordinate to  $\{U, V\}$ . Extend  $\rho_U \zeta$  by 0 to a k-1-form  $\zeta_V$  to all of V (same for U). Choose  $(-\zeta_U, \zeta_V)$  in the pre-image of  $\zeta$  under j.
- 2. Apply d to obtain  $(-d\zeta_U, d\zeta_V)$ . Since  $\zeta$  is closed and j is a chain map  $j(-d\zeta_U, d\zeta_V) = dj(-\zeta_U, \zeta_V) = d\zeta = 0$ . Hence the difference of  $-d\zeta_U$  and  $d\zeta_V$  vanishes on  $U \cap V$  (even though of course  $\zeta_U + \zeta_V = \zeta$  which does not vanish in general.).
- 3. Hence  $-d\zeta_U$  and  $d\zeta_V$  can be glued to a global k-form, which is why  $(-d\zeta_U, d\zeta_V)$  has a pre-image  $\alpha$  under i. The form  $\alpha$  is both an extension of  $-d\zeta_U$  from U to M and of  $d\zeta_V$  from V to M.
- 4. Since  $(-d\zeta_U, d\zeta_V)$  is exact and i is a chain map and injective,  $\alpha$  is closed.

Often the dimension of the cohomology groups alone gives a lot of information about the manifold. The following Lemma gives a restriction:

#### Lemma 1. Let

$$0 \xrightarrow{d_{-1}} A^0 \xrightarrow{d_0} A^1 \xrightarrow{\delta} \dots \xrightarrow{d_{m-1}} A^m \xrightarrow{d_m} 0$$
 (22)

be a long exact sequence with dim  $A^k < \infty$  for every  $k \in \mathbb{Z}$ . Then

$$\sum_{k=0}^{m} (-1)^k \dim A^k = 0. \tag{23}$$

*Proof.* We use the rank-nullity theorem dim  $A^k = \dim \ker d_k + \dim \operatorname{im} d_k$  and the exactness of the sequence im  $d_k = \ker d_{k+1}$  to compute

$$\sum_{k=0}^{m} (-1)^k \dim A^k = \sum_{k=0}^{m} (-1)^k (\dim \ker d_k + \dim \operatorname{im} d_k)$$

$$= \sum_{k=0}^{m-1} (-1)^k (\dim \ker d_k + \dim \ker d_{k+1}) + (-1)^m \dim A^m$$

$$= \dim \ker d_0 + (-1)^{m-1} \dim \ker d_m + (-1)^m \dim A^m = 0$$

Since  $d_0$  is injective, the first term is 0 and since  $(-1)^{m-1}$  dim ker  $d_m + (-1)^m$  dim  $A^m$  the second two terms vanish.

Remark. The above Lemma ?? can be slightly weakened in that the assumption of  $\dim A^k < \infty$  can be dropped for every third term in the sequence. In that case, one can conclude that those spaces are also finite dimensional. To see this, note that via rank-nullity

$$\dim A^k = \dim \ker d_k + \dim \operatorname{im} d_k \tag{24}$$

$$= \dim \operatorname{im} d_{k-1} + \dim \ker d_{k+1} \tag{25}$$

$$\leq \dim A^{k-1} + \dim A^{k+1} < \infty. \tag{26}$$

In particular, in the setting of the Mayer-Vietoris sequence, this implies that if U, V and  $U \cap V$  have finite dimensional deRham cohomology, then so does M.

**Proposition 3.** In the situation as above, if U, V, and  $U \cap V$  are connected, then

(i) the sequence

$$0 \to H^0(M) \xrightarrow{i} H^0(U) \oplus H^0(V) \xrightarrow{j} H^0(U \cap V) \to 0 \tag{27}$$

is short exact and M is connected.

(ii) the long exact sequence

$$0 \to H^1(M) \xrightarrow{i} H^1(U) \oplus H^1(V) \xrightarrow{j} H^1(U \cap V) \to \dots$$
 (28)

is also exact.

*Proof.* (i) By the exactness of the Mayer-Vietoris sequence, we only need to show that  $j^*$  is surjective. To see this, recall that  $H^0(U) \oplus H^0(V)$  and  $H^0(U \cap V)$  consists of pairs of functions, each constant on U, V, and  $U \cap V$ , respectively, and j assigns to any pair the difference of the restrictions to  $U \cap V$ . Thus, any constant function on  $U \cap V$  with value  $a \in \mathbb{R}$  is the image of (a, 0) under the map  $j^*$ .

From Lemma ?? and the exactness of (??) we get  $\dim H^0(M) - 2 + 1 = 0$ , thus  $\dim H^0(M) = 1$  and hence that M is connected. A point-set-topological proof is of course also possible.

(ii) By (i), the map  $\delta^*: H^0(U \cap V) \to H^1(M)$  is the zero map. Hence  $H^0(U \cap V)$  may be replaced by the zero map.

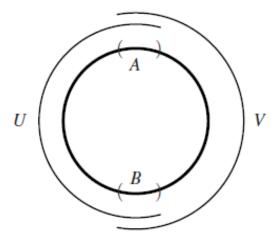

Figure 2: Covering of  $\mathbb{S}^1$ . Fig. 26.2 [TuMf].

# 2. Computations

# 2.1. Cohomology of $\mathbb{S}^1$

Using homotopy invariance of de Rham cohomology we note that  $U \coprod V \simeq \mathbb{R} \coprod \mathbb{R}$  and  $U \cap V \simeq \mathbb{R} \coprod \mathbb{R}$ . Hence the second and third column are determined. For  $H^0(\mathbb{S}^1) = 0$ , recall that the dimension of  $H^0(M)$  equals the number of connected components of M, which in this case is 1.

Thus we are left with the following table of cohomology groups:

By Mayer-Vietoris we have the following exact sequence:

$$0 \to \mathbb{R} \xrightarrow{i^*} \mathbb{R} \oplus \mathbb{R} \xrightarrow{j^*} \mathbb{R} \oplus \mathbb{R} \xrightarrow{\delta^*} H^1(\mathbb{S}^1) \to 0$$
 (29)

Using Lemma ??, we obtain from (??)

$$1 - 2 + 2 - \dim H^1(\mathbb{S}^1) = 0 \tag{30}$$

and thus dim  $H^1(\mathbb{S}^1) \cong \mathbb{R}$ .

In order to identify a generator of  $H^1(\mathbb{S}^1)$ , recall from the last talk that for a closed, orientable manifold, the volume form gives a closed, but not exact form of degree  $\dim(M)$ . Hence in this case,  $H^1(\mathbb{S}^1)$  is generated by  $\theta$ .

Another way of identifying a generator of  $H^1(\mathbb{S}^1)$  is to compute it explicitly: since (??) is exact at  $H^1(\mathbb{S}^1)$  we have  $H^1(\mathbb{S}^1) = \operatorname{im} \delta^*$ .

Consider the cohomology class  $[f] \in H^0(U \cap V)$ , which is represented by the smooth function  $f \in C^{\infty}(\mathbb{S}^1)$  which is 1 on the connected component containing

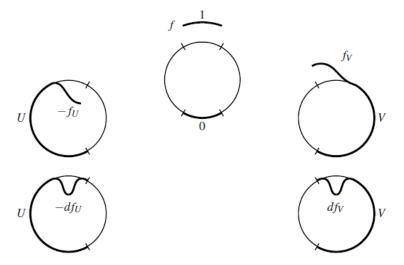

Figure 3: Connecting homomorphism  $\delta^*: H^0(U\cap V)\to H^1(\mathbb{S}^1)$ . Fig. 26.3 [TuMf].

the north pole and 0 on the connected component containing the south pole. Then apply  $\delta^*: i^{-1} \circ d \circ j^{-1}$ .

Firstly,  $j^{-1}(f) = (-f_U, f_V)$  gives a function on U and V, respectively, which is an extension of  $-\rho_V f$  from  $U \cap V$  to U and  $\rho_U f$  from  $U \cap V$  to V, respectively. Applying d gives two bump functions, each supported on the connected component containing the north pole, and coinciding on all of  $U \cap V$ . Applying  $i^{-1}$  gives a smooth one form on  $\mathbb{S}^1$ , whose restriction to U and V is  $-df_U$  and  $df_V$  on U and V respectively, and is thus only has support in the connected component of  $U \cap V$  containing the north pole.

## **2.2.** Cohomology of $\mathbb{S}^n$ , $n \geq 2$

**Theorem 2.** Let  $n \geq 1$ . Then

$$H^{k}(\mathbb{S}^{n}) = \begin{cases} \mathbb{R} & k = 0, n \\ 0 & else. \end{cases}$$
 (31)

*Proof.* n = 1: see subsection ??

 $n\Rightarrow n+1$ : Assume the claim holds for  $\mathbb{S}^n$ . There exists an open covering of  $\mathbb{S}^{n+1}$  by two discs  $\mathbb{D}^n$  of dimension n (these are the two standard charts obtained by stereographic projection from the north and from the south pole). The intersection of the two is homeomorphic to  $\mathbb{S}^n$ . Thus, the Mayer-Vietoris sequence, the induction hypothesis, and the fact that the dimension of  $H^0(\mathbb{S}^n)$  equals the number of connected components, give that the following is an exact sequence.

Figure 4: Covering of the torus. Fig. 28.1. [TuMf].

	$\mathbb{S}^{n+1}$	$\mathbb{D}^{n+1} \coprod \mathbb{D}^{n+1}$	$\mathbb{S}^n$
$H^{n+1}$	$H^{n+1}(\mathbb{S}^{n+1})$	0	0
$H^n$	$H^n(\mathbb{S}^{n+1})$	0	$\mathbb{R}$
$H^{n-1}$	$H^{n-1}(\mathbb{S}^{n+1})$	0	0
:	:	:	:
$H^1$	$H^1(\mathbb{S}^{n+1})$	0	0
$H^0$	$\mathbb{R}$	$\mathbb{R}\oplus\mathbb{R}$	$\mathbb{R}$

In particular, this gives that

$$0 \to \mathbb{R} \to H^{n+1}(\mathbb{S}^{n+1}) \to 0 \tag{32}$$

and

$$0 \to 0 \to H^k(\mathbb{S}^{n+1}) \to 0, \quad 2 \le k \le n-1 \tag{33}$$

are exact and hence  $H^{n+1}(\mathbb{S}^{n+1}) \cong \mathbb{R}$  and  $H^k(\mathbb{S}^{n+1}) = 0$ . Furthermore, Lemma ?? shows that  $H^1(\mathbb{S}^{n+1}) = 0$ .

## 2.3. Cohomology Vector Space of the Torus

Choose a covering of the torus as follows:

Then A and B have the homotopy type of  $\mathbb{S}^1$  and thus their cohomology is isomorphic. This gives

$$\begin{array}{c|cccc} & \mathbb{S}^1 & U \coprod V & U \cap V \\ \hline H^2 & H^2(M) & 0 & 0 \\ H^1 & H^1(\mathbb{S}^1) & \mathbb{R} \oplus \mathbb{R} & \mathbb{R} \oplus \mathbb{R} \\ H^0 & \mathbb{R} & \mathbb{R} \oplus \mathbb{R} & \mathbb{R} \oplus \mathbb{R} \end{array}$$

Now, Lemma ?? gives

$$1 - 2 + 2 - \dim H^1(M) + 2 - 2 + \dim H^2(M) = 0 \implies \dim H^1(M) = \dim H^2(M) + 1,$$
(34)

and furthermore the exactness of the sequence gives

$$H^{2}(M) = \operatorname{im} \delta_{1}^{*} \cong (\mathbb{R} \oplus \mathbb{R}) / \ker \delta_{1}^{*} \cong (\mathbb{R} \oplus \mathbb{R}) / \operatorname{im} j^{*}. \tag{35}$$

Thus the computation boils down to understanding the image of  $j^*$ . Recall that  $j^*$  is defined by

$$j^*(\omega, \eta) = (j_U^* \omega)|_{U \cap V} - (j_V^* \eta)|_{U \cap V}$$
(36)

where  $j_U^*\omega$  and  $j_V^*\eta$  are restrictions of  $\omega$  and  $\eta$  from U, resp. V, to  $U \cap V$ . In our case, observe that

$$j^*(\theta_A, \theta_B) = (\theta_A - \theta_B, \theta_A - \theta_B), \tag{37}$$

which gives im  $j^* \cong \mathbb{R}$ . Thus  $H^2(M) \cong \mathbb{R}$  and hence  $H^1(M) \cong \mathbb{R} \oplus \mathbb{R}$ .

### 2.4. Cohomology Ring of the Torus

In order to obtain more refined statements about the cohomology of the torus, we use the fact that one can obtain  $T^2$  as a quotient of  $\mathbb{R}^2$  (on which one knows the cohomology well). In particular, with  $\Lambda := \mathbb{Z}^2$ , we have

$$T^2 = \mathbb{R}^2 / \Lambda. \tag{38}$$

Note that since  $\pi: \mathbb{R}^2 \to T^2$  is the quotient of a smooth manifold by the smooth, proper, and free action of a discrete Lie Group  $\Lambda$ , the map  $\pi$  is a normal covering and in particular is a local diffeomorphism.

For a  $\lambda \in \Lambda$  define the translation function  $l_{\lambda} : \mathbb{R}^2 \to \mathbb{R}^2$  via  $l_{\lambda}(q) = q + \lambda$ . Then we have to following Proposition.

**Proposition 4.** The pullback  $\pi^*: \Omega(T^2) \to \Omega(\mathbb{R}^2)$ , induced by the projection  $\pi: \mathbb{R}^2 \to T^2$ , is injective and

$$\pi^*(\Omega^*(T^2)) = \{ \omega \in \Omega^*(\mathbb{R}^2) : l_{\lambda}^*(\omega) = \omega, \forall \lambda \in \Lambda \}.$$
 (39)

*Proof.* More generally, let  $\pi: M \to N$  be a surjective submersion i.e. a smooth function s.t.  $\pi_*: T_pM \to T_{\pi(p)}N$  is a surjection for every  $p \in M$ . Let  $\omega \in \Omega^k(N)$  s.t.  $\pi^*(\omega) = 0 \in \Omega^k(M)$ , let  $w_1, \ldots, w_k \in T_qN$  be arbitrary, choose a point  $p \in \pi^{-1}q \subseteq M$  and define  $v_i := \pi_*^{-1}(w_i)$ . Then we have

$$\omega(w_1, \dots, w_k) = \omega(\pi_*(v_1), \dots, \pi_*(v_k)) = \pi^*(\omega)(v_1, \dots, v_k) = 0,$$
 (40)

i.e.  $\omega = 0$ .

For the " $\subseteq$ " -inclusion of the characterization of the image of  $\pi^*$ , note that for any  $\lambda \in \Lambda$  and any  $q \in \mathbb{R}^2$  we have

$$(\pi \circ l_{\lambda})(q) = \pi(q + \lambda) = \pi(q), \tag{41}$$

i.e.  $\pi \circ l_{\lambda} = \pi$  and thus by functoriality  $\pi^* = l_{\lambda}^* \circ \pi^*$ , showing that for any  $\omega \in \Omega(T^2)$ 

$$\pi^* \omega = l_{\lambda}^* \circ \pi^* \omega. \tag{42}$$

For the "\geq"-inclusion, assume that  $\bar{\omega} \in \Omega^k(\mathbb{R}^2)$  is invariant under  $l_{\lambda}^*$  for any  $\lambda \in \Lambda$ . For any  $p \in T^2$  and  $v_1, \ldots, v_k \in T_pT^2$ , define

$$\omega_p(v_1, \dots, v_k) := \bar{\omega}_{\bar{p}}(\bar{v}_1, \dots, \bar{v}_k) \tag{43}$$

for a choice of  $\bar{p} \in \pi^{-1}(p)$  and  $\bar{v}_1, \ldots, \bar{v}_k \in T_{\bar{p}} \mathbb{R}^2$  s.t.  $\pi_* \bar{v}_i = v_i$ . Note that if  $\bar{p}$  is chosen, there is a unique choice for  $\bar{v}_1, \ldots, \bar{v}_k$  since  $\pi_*$  is an isomorphism on each tangent space. Hence, in order to show well definedness of  $\omega$ , we only need to show independence of the choice of  $\bar{p}$ . To do this, let  $\tilde{p} = \bar{p} + \lambda$ ,  $\lambda \in \Lambda$  be another point in  $\pi^{-1}(p)$ . By the invariance under  $l_{\lambda}^*$  we have

$$\bar{\omega}_{\bar{p}} = (l_{\lambda}^* \bar{\omega})_{\bar{p}} = l_{\lambda}^* (\bar{\omega}_{\bar{p}+\lambda}). \tag{44}$$

and thus

$$\bar{\omega}_{\bar{p}}(\bar{v}_1, \dots, \bar{v}_k) = l_{\lambda}^*(\bar{\omega}_{\bar{p}+\lambda})(\bar{v}_1, \dots, \bar{v}_k) \tag{45}$$

$$= \bar{\omega}_{\bar{p}+\lambda}(l_{\lambda*}\bar{v}_1, \dots, l_{\lambda*}\bar{v}_k). \tag{46}$$

Since  $\pi \circ l_{\lambda} = \pi$  we have  $\pi_* \circ l_{\lambda*} = \pi_*$  and hence (??) shows that  $\omega_p$  is independent of the choice of  $\bar{p}$ . Finally, by definition of  $\omega$  we have

$$\bar{\omega}_{\bar{p}}(\bar{v}_1, \dots, \bar{v}_k) = \omega_{\pi(\bar{p})}(\pi_* \bar{v}_1, \dots, \pi_* \bar{v}_k) = (\pi^* \omega)_{\bar{p}}(\bar{v}_1, \dots, \bar{v}_k). \tag{47}$$

Hence, 
$$\bar{\omega} = \pi^* \omega$$
.

We will now explicitly describe the ring structure on  $H^*(T^2)$ .

Let x, y be the standard coordinate maps on  $\mathbb{R}^2$ . Then for any  $\lambda \in \Lambda$  we have

$$l_{\lambda}^*(dx) = d(l_{\lambda}^*x) = d(x+\lambda) = dx \tag{48}$$

and thus by Proposition ??, both dx and dy arise as pullbacks of forms  $\alpha$  and  $\beta$  on  $T^2$ . Furthermore we have

$$\pi^*(d\alpha) = d(\pi^*\alpha) = d(dx) = 0. \tag{49}$$

Since  $\pi^*$  was injective,  $\alpha$  is closed and thus defines a class in  $H^1(T^2)$ .

**Proposition 5.** The forms  $1, \alpha, \beta, \alpha \wedge \beta$  represent a basis of  $H^*(T^2)$ .

*Proof.* Let  $I^2 := [0,1]^2$ , let  $i: I^2 \hookrightarrow \mathbb{R}^2$  be the canonical inclusion and define  $F := \pi \circ i: I^2 \to T^2$ . Then  $F^*\alpha = i^*(\pi^*\alpha) = i^*dx$  is the restriction of dx to unit square.

We compute:

$$\int_{M} \alpha \wedge \beta = \int_{F(I^{2})} \alpha \wedge \beta = \int_{I^{2}} F^{*}(\alpha \wedge \beta) = \int_{I^{2}} dx \wedge dy = \int_{0}^{1} \int_{0}^{1} dx dy = 1.$$
 (50)

Thus, the form  $\alpha \wedge \beta$  represents a non-zero cohomology class, since otherwise by Stokes, the above integral were 0. Since dim  $H^2(T^2) = 1$  we conclude that

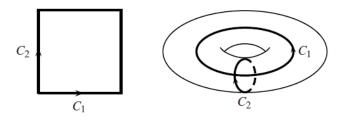

Figure 5: Parametrization and curves on the torus. Fig. 28.2. [TuMf].

 $[\alpha \wedge \beta]$  forms a basis of  $H^2(T^2)$ .

In order to see that  $\alpha, \beta$  form a basis of  $H^1(T^2)$ , consider the two maps  $i_1, i_2 : I \to \mathbb{R}$  given by  $i_1(t) = (t, 0)$  and  $i_2(t) = (0, t)$ . The two curves induce two closed curves  $C_1, C_2$  in  $T^2$  via  $C_k = \pi \circ i_k$ . Furthermore

$$C_1^* \alpha = i_1^* \pi^* \alpha = i_1^* dx = di_1^* x = dt$$
  
 $C_1^* \beta = i_1^* \pi^* \beta = i_1^* dy = di_1^* y = 0$ 

and thus

$$\int_{C_1} \alpha = \int_{C_1(I)} \alpha = \int_I C_1^* \alpha = \int_0^1 dt = 1$$

$$\int_{C_1} \beta = \int_{C_1(I)} \beta = \int_I C_1^* \beta = \int_0^1 0 = 0$$

A similar argument is true for  $C_2$  giving  $\int_{C_2} \beta \neq 0$ . Thus, neither  $\alpha$  nor  $\beta$  is exact on  $T^2$ , and hence both define non-trivial cohomology classes  $[\alpha]$  and  $[\beta]$ . The two classes are linearly independent as otherwise  $\int_{C_2} \alpha \neq 0 \Rightarrow \int_{C_2} \beta = 0$  which is not true.

Since  $T^2$  is connected,  $H^0(T^2)$  is one-dimensional and thus generated by the cohomology class induced by the constant function.

In conclusion, the algebra  $H^*(T^2)$  is isomorphic to

$$\bigwedge(a,b) = T(\mathbb{R} x \oplus \mathbb{R} y)/(x^2, y^2, xy + yx), \quad \deg(x) = \deg(y) = 1$$
 (51)

where T(V) is the tensor algebra on the vector space V and  $\mathbb{R} x \oplus \mathbb{R} y$  is the two dimensional, real vector space generated by x and y. This algebra is called the **exterior algebra of degree 1**.

Figure 6: Punctured compact oriented surface M. Fig. 28.3. [TuMf].

# 2.5. Cohomology of Genus g-Surfaces

**Lemma 2.** Let M be a compact, oriented surface, let  $p \in M$  and let  $i : \mathbb{S}^1 \to M \setminus \{p\}$  be the inclusion of a small circle around the puncture. Then the restriction map

$$i^*: H^1(M \setminus \{p\}) \to H^1(\mathbb{S}^1) \tag{52}$$

is the zero map.

*Proof.* Let  $\omega \in \Omega^1(M \setminus \{p\})$  be closed and let  $D \subseteq M$  be an open disc in M bounded by  $C = i(\mathbb{S}^1)$ . Then

$$\int_{\mathbb{S}^1} i^* \omega = \int_{\partial(M \setminus D)} \omega = \int_{M \setminus D} \underbrace{d\omega}_{=0} = 0$$
 (53)

Since  $H^1(\mathbb{S}^1) \cong \mathbb{R}$ , with the isomorphism given by integration, this shows that  $i^*[\omega] = 0$ 

**Proposition 6.** Let  $T^2$  be a torus and let  $p \in T^2$ . Then  $A := T^2 \setminus \{p\}$  has the following cohomology:

$$H^{k}(A) = \begin{cases} \mathbb{R} & , & k = 0 \\ \mathbb{R}^{2} & , & k = 1 \\ 0 & , & k \ge 2. \end{cases}$$
 (54)

*Proof.* Cover  $T^2$  by A and an open disk U around p. Since A, U, and  $U \cap V$  are connected, by Proposition ??, we may start the Mayer-Vietoris sequence with  $H^1(T^2)$ . Using  $A \cap U \simeq \mathbb{S}^1$  and  $U \simeq \{*\}$ , we obtain

$$\begin{array}{c|cccc} & T^2 & A \coprod U & A \cap U \\ \hline H^2 & \mathbb{R} & H^2(A) \oplus 0 & 0 \\ H^1 & \mathbb{R} \oplus \mathbb{R} & H^1(A) \oplus 0 & \mathbb{R} \end{array}$$

Since  $H^1(U) = 0$ , the difference map  $j^*$  on the level of  $H^1$  is simply the restriction map and by Lemma ?? this restriction is 0. Hence, on the level of  $H^1$ , the morphism  $i^*$  is an isomorphism i.e.

$$H^1(A) \cong \mathbb{R} \oplus \mathbb{R},\tag{55}$$

and furthermore the following sequence is exact:

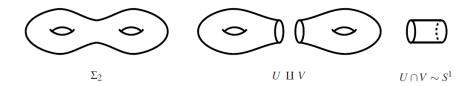

Figure 7: Covering of  $\Sigma_2$ . Fig. 28.4. [TuMf].

$$0 \to \mathbb{R} \to \mathbb{R} \to H^2(A) \to 0 \tag{56}$$

and thus by dimension counting (i.e. Lemma ??) we conclude  $H^2(A) = 0$ .  $\square$ 

**Proposition 7.** (cohomology of genus g surface) Let  $g \geq 0$  and let  $\Sigma_g$  denote a compact, orientable surface of genus g. Then

$$H^{k}(\Sigma_{g}) = \begin{cases} \mathbb{R} & , & k = 0 \\ \mathbb{R}^{2g} & , & k = 1 \\ \mathbb{R} & , & k = 2 \\ 0 & , & k \ge 3. \end{cases}$$
 (57)

*Proof.* The proof will proceed via induction. The base case  $\Sigma_0 = \mathbb{S}^2$  is covered by subsection ??.

For the induction on g, assume  $H^*(\Sigma_g)$  according to equation  $(\ref{eq:condition})$ . Similarly to Proposition  $\ref{eq:condition}$ , let us first compute the cohomology of the punctured genus g surface  $A_g := \Sigma_g \setminus \{p\}$ . As for the torus,cover  $\Sigma_g$  by  $A_g$  and a small disc U around the puncture. Then since the  $A_g$ , U and  $A_g \cap U$  are connected, by Proposition  $\ref{eq:condition}$ , we may start the Mayer-Vietoris sequence with  $H^1(\Sigma_g)$ . As with the torus, using that  $U \simeq \{*\}$  and  $A_g \cap U \simeq \mathbb{S}^1$ , we get

$$\begin{array}{c|cccc} & \Sigma_g & A_g \coprod U & A_g \cap U \\ \hline H^2 & \mathbb{R} & H^2(A) \oplus 0 & 0 \\ H^1 & \mathbb{R}^{2g} & H^1(A) \oplus 0 & \mathbb{R} \end{array}.$$

Again,  $j^*$  is simply the restriction, which, by Lemma ??, is the 0-map. Hence we have

$$\mathbb{R}^{2g} \cong H^1(A) \tag{58}$$

and by dimension counting  $H^2(A) = 0$ .

Now, for the computation of  $H^*(\Sigma_{g+1})$ , cover  $\Sigma_{g+1}$  with  $A_g$  and the punctured torus  $A_1$ , with  $A_g \cap A_1$  is homeomorphic to a cylinder (which is in turn homotopy equivalent to  $\mathbb{S}^1$ ). Since  $\Sigma_{g+1}$  is connected,  $H^0(\Sigma_{g+1}) = 0$ . On the one hand, since the map  $H^2(\Sigma_{g+1}) \to 0$  has as its kernel all of  $H^2(\Sigma_{g+1})$ , the map  $\mathbb{R} \to H^2(\Sigma_{g+1})$  must be surjective. Hence  $\dim(H^2(\Sigma_{g+1})) \leq 1$ . On the other hand,  $\Sigma_{g+1}$  is an oriented closed manifold, and thus admits a volume form, which, by

Stokes, is not exact. Hence  $\dim(H^2(\Sigma_{g+1}) \geq 1$  and thus  $\dim(H^2(\Sigma_{g+1})) = 1$ . Finally, dimension counting via Proposition ?? gives  $\dim(H^1(\Sigma_{g+1})) = 2(g+1)$ .

# 3. Some classical applications

We want to show

**Theorem 3.** (Jordan-Brouwer separation) Let  $n \geq 2$  and  $\Sigma \subseteq \mathbb{R}^n$  be homeomorphic to  $\mathbb{S}^{n-1}$ . Then

- 1.  $\mathbb{R}^2 \setminus \Sigma$  has exactly 2 connected components,  $U_1$  and  $U_2$ , one of which being bounded and one of which being unbounded,
- 2.  $\Sigma$  is the boundary of both  $U_1$  and  $U_2$ .

We say that  $U_1$  is the domain **inside**  $\Sigma$  and  $U_2$  is the domain **outside**  $\Sigma$ .

Before proving this, we need a couple of Lemmas though. Firstly, recall the Tietze extension theorem:

**Theorem 4.** (Tietze Extension) Let  $A \subseteq \mathbb{R}^n$  be closed and let  $f: A \to \mathbb{R}^m$  be continuous, then there exists a continuous function  $\tilde{f}: \mathbb{R}^n \to \mathbb{R}^m$  s.t.  $\tilde{f}|_A = f$ .

*Remark.* The theorem is usually stated more generally with  $\mathbb{R}^n$  replaced by an arbitrary normal topological space X and is actually equivalent to the normality of X

**Lemma 3.** Let  $A \subseteq \mathbb{R}^n$  and  $B \subseteq \mathbb{R}^m$  be closed sets and let  $\phi : A \to B$  be a homeomorphism. Then there is a homeomorphism  $h : \mathbb{R}^{n+m} \to \mathbb{R}^{n+m}$  s.t. for every  $x \in A$ 

$$h(x, 0_m) = (0_n, \phi(x)). \tag{59}$$

where  $0_k$  is the 0 in the first k components.

*Proof.* By the Tietz extension theorem ?? one can extend  $\phi$  to a continuous function  $\tilde{\phi}: \mathbb{R}^n \to \mathbb{R}^m$ . Define firstly a homeomorphism  $h_1: \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^n \times \mathbb{R}^m$  by

$$h_1(x,y) = (x, y + \tilde{\phi}(x)).$$
 (60)

Analogously, one can extend  $\psi := \phi^{-1}$  to a continuous function  $\tilde{\psi} : \mathbb{R}^m \to \mathbb{R}^n$  and define  $h_2 : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^n \times \mathbb{R}^m$  via

$$h_2(x,y) = (x + \tilde{\psi}(y), y).$$
 (61)

Define  $h := h_2^{-1} \circ h_1$ . Then for every  $x \in A$  we have

$$h(x, 0_m) = h_2^{-1}(h_1(x, 0_m)) = h_2^{-1}(x, \tilde{\phi}(x))$$
(62)

$$= (x - \tilde{\psi}(\tilde{\phi}(x), \tilde{\phi}(x))) = (x - \psi(\phi(x)), \phi(x))$$

$$(63)$$

$$= (x - x, \phi(x)) = (0, \phi(x)). \tag{64}$$

**Corollary 1.** Any homeomorphism  $\phi: A \to B$  between closed sets  $A, B \subseteq \mathbb{R}^n$  can be extended to a homeomorphism  $\tilde{\phi}: \mathbb{R}^{2n} \to \mathbb{R}^{2n}$ .

*Proof.* Compose the homeomorphism h from Lemma ?? with the homeomorphism which exchanges the first n components with the second n.

Remark. Note that by restricting  $\tilde{\phi}$  to  $\mathbb{R}^{2n} \setminus A$  we obtain a homeomorhism  $\mathbb{R}^{2n} \setminus A \to \mathbb{R}^{2n} \setminus B$ . But note that this does **not** imply, and it is generally false, that  $\mathbb{R}^n \setminus A \to \mathbb{R}^n \setminus B$  are homeomorphic. In fact, this would contradict the existence of the Alexander horned sphere  $\Sigma$  in  $\mathbb{R}^3$ : even though  $\Sigma$  is homeomorphic to  $\mathbb{S}^2$ , its complement,  $\mathbb{R}^3 \setminus \Sigma$ , is not homeomorphic to  $\mathbb{R}^3 \setminus \Sigma^2$ , as the former is not simply connected. However, the abelianization of  $\pi_1(\mathbb{R}^3 \setminus \Sigma)$  is 0, which is why the following theorem does not pose a contradiction.

**Proposition 8.** Let  $A \subseteq \mathbb{R}^n$  be closed. Then we have

$$H^{p+1}(\mathbb{R}^{n+1} \setminus A) \cong H^{p}(\mathbb{R}^{n} \setminus A), \quad p \geq 1,$$
  
$$H^{1}(\mathbb{R}^{n+1} \setminus A) \cong H^{0}(\mathbb{R}^{n} \setminus A) / \mathbb{R} \cdot 1$$
  
$$H^{0}(\mathbb{R}^{n+1} \setminus A) \cong \mathbb{R} \cdot 1.$$

*Proof.* Identify  $\mathbb{R}^{n+1} = \mathbb{R}^n \times \mathbb{R}$  and define the following two sets

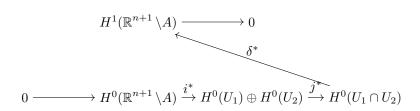

$$U_1 := \mathbb{R}^n \times (0, \infty) \cup (\mathbb{R}^n \setminus A) \times (-1, \infty)$$
  
$$U_2 := \mathbb{R}^n \times (-\infty, 0) \cup (\mathbb{R}^n \setminus A) \times (-\infty, 1)$$

Then we have  $U_1 \cup U_2 = \mathbb{R}^{n+1} \setminus A$  and  $U_1 \cap U_2 = (\mathbb{R}^n \setminus A) \times (-1,1)$ . Define by  $\phi(x_1, \ldots, x_{n+1}) = (x_1, \ldots, x_n, x_{n+1} + 1)$ . Then for every  $x \in U_1$ , the set  $U_1$  contains a line segment from x to  $\phi(x)$  and from  $\phi(x)$  to a point  $p \in \mathbb{R}^n \times (0, \infty)$ . Maybe draw a picture with n = 1 to convince yourself of that. Hence  $U_1$  is contractible (to the point p). Analogously,  $U_2$  is contractible.

Note that  $\mathbb{R}^n \setminus A$  deformation retracts to  $U_1 \cap U_2$  and hence their cohomology is isomorphic. By the Mayer-Vietoris sequence we obtain an isomorphism via the connecting homomorphism

$$\delta^*: H^p(U_1 \cap U_2) \to H^{p+1}(\mathbb{R}^{n+1} \setminus A) \tag{65}$$

for  $p \ge 1$ . For the second isomorphism consider the following exact sequence, obtained via Mayer-Vietoris:

Elements in  $H^0(U_1) \oplus H^0(U_2)$  are given by pairs of constant functions on  $U_1$  and  $U_2$  with values  $a_1$  and  $a_2$ . The image of  $(a_1, a_2)$  is thus the constant function on  $U_1 \cap U_2$  with value  $a_1 - a_2$ . Thus by the exactness of Mayer-Vietoris sequence

$$\ker \delta^* = \operatorname{im} j^* = \mathbb{R} \cdot 1, \tag{66}$$

where 1 is the constant function on  $U_1 \cap U_2$  with value 1. Thus we obtain

$$H^{1}(\mathbb{R}^{n+1} \setminus A) \cong H^{0}(U_{1} \cap U_{2}) / \ker \delta^{*} \cong H^{0}(\mathbb{R}^{n} \setminus A) / \mathbb{R} \cdot 1. \tag{67}$$

We also have by the above Mayer-Vietoris sequence and its exactness

$$\dim H^0(\mathbb{R}^{n+1} \setminus A) = \dim(\operatorname{im} i^*) = \dim(\ker j^*) = 1 \tag{68}$$

and thus 
$$H^0(\mathbb{R}^{n+1} \setminus A) \cong \mathbb{R}$$
.

**Theorem 5.** Let  $A, B \subsetneq \mathbb{R}^n$  be closed subsets s.t. A and B are homeomorphic. Then

$$H^p(\mathbb{R}^n \setminus A) \cong H^p(\mathbb{R}^n \setminus B), \quad p \ge 0.$$
 (69)

*Proof.* Applying Proposition ??  $m \ge 1$  times yields

$$H^{p+m}(\mathbb{R}^{n+m} \setminus A) \cong H^p(\mathbb{R}^n \setminus A) \tag{70}$$

$$H^{m}(\mathbb{R}^{n+m} \setminus A) \cong H^{0}(\mathbb{R}^{n} \setminus A) / \mathbb{R} \cdot 1. \tag{71}$$

The same is true for B. By corollary ?? we know that  $\mathbb{R}^{2n} \setminus A$  and  $\mathbb{R}^{2n} \setminus B$  are homeomorphic and thus have the same de Rham cohomology. Thus

$$H^p(\mathbb{R}^n \setminus A) \cong H^{p+n}(\mathbb{R}^{2n} \setminus A) \cong H^{p+n}(\mathbb{R}^{2n} \setminus B) \cong H^p(\mathbb{R}^n \setminus B), \quad p \ge 1.$$
 (72)

and

$$H^0(\mathbb{R}^n \setminus A) / \mathbb{R} \cdot 1 \cong H^n(\mathbb{R}^{2n} \setminus A) \cong H^n(\mathbb{R}^{2n} \setminus B) \cong H^0(\mathbb{R}^n \setminus B) / \mathbb{R} \cdot 1. \tag{73}$$

**Corollary 2.** Let A, B be two closed homeomorphic subsets of  $\mathbb{R}^n$ . Then  $\mathbb{R}^n \setminus A$  and  $\mathbb{R}^n \setminus B$  have the same number of connected components.

*Proof.* If  $A = B = \mathbb{R}^n$  this is clear. If  $A \neq \mathbb{R}^n$  and  $B \neq \mathbb{R}^n$ , this follows from theorem ??. If  $A = \mathbb{R}^n$  but  $B \neq \mathbb{R}^n$ , then considering A and B as closed subsets of  $\mathbb{R}^{n+1}$  and applying theorem ?? again yields

$$2 = \dim H^0(\mathbb{R}^{n+1} \setminus A) = \dim H^0(\mathbb{R}^{n+1} \setminus B) = 1 \tag{74}$$

a contradiction. Hence A and B cannot be homeomorphic to begin with.  $\Box$ 

Now let us turn to the proof of the Jordan-Brouwer separation theorem ??:

*Proof.* (i) Since  $\mathbb{S}^{n-1}$  is compact, so is  $\Sigma$  and thus  $\Sigma$  is closed in  $\mathbb{R}^n$ . Since  $\mathbb{S}^{n-1}$  separates  $\mathbb{R}^n$  into the two connected components

$$int(\mathbb{D}^n) = \{x \in \mathbb{R}^n : ||x|| < 1\} \text{ and } W := \{x \in \mathbb{R}^n : ||x|| > 1\}$$
 (75)

by corollary ??,  $\mathbb{R}^n \setminus \Sigma$  also has two connected components. Furthermore, with  $r := \max_{x \in \Sigma} \|x\|$ , the connected set  $r \cdot W$  is contained in one of the two connected components  $U_2$  of  $\mathbb{R}^n \setminus \Sigma$ , which is thus unbounded. Hence for the other component,  $U_1$ , we have

$$U_1 \subseteq \mathbb{R}^n \setminus U_2 = \{ x \in \mathbb{R}^n : ||x|| \le r \}. \tag{76}$$

Thus  $U_1$  is bounded.

(ii) Let  $p \in \Sigma$  and let  $V \subseteq \mathbb{R}^n$  be an arbitrary open neighborhood of p. Then the set  $A := \Sigma \setminus (\Sigma \cap V)$  is closed in  $\Sigma$  and homeomorphically mapped to a proper, closed subset B of  $\mathbb{S}^{n-1}$ . Since  $\mathbb{S}^{n-1}$  is closed in  $\mathbb{R}^n$ , the set  $B = \mathbb{S}^{n-1} \cap B$  is closed in  $\mathbb{R}^n$ . Furthermore, since B is a proper subset of  $\mathbb{S}^{n-1}$  we see that  $\mathbb{R}^n \setminus B$  is connected, and thus by corollary ?? so is  $\mathbb{R}^n \setminus A$ . Since  $\mathbb{R}^n \setminus A$  is an open subset of  $\mathbb{R}^n$  and connected, it is path-connected. Hence for any  $p_1 \in U_1$  and  $p_2 \in U_2$  one can find a continuous curve  $\gamma : [0,1] \to \mathbb{R}^n \setminus A$  s.t.  $\gamma(0) = p_1$  and  $\gamma(1) = p_2$ . By (i), the curve  $\gamma$  (now considered as a curve into  $\mathbb{R}^n$ ) has to intersect  $\Sigma$ , since otherwise  $U_1$  and  $U_2$  would lie in a common path component. The set  $\gamma^{-1}(\Sigma) \subseteq [0,1]$  is closed, hence compact, and hence contains  $c_1 = \min \gamma^{-1}(\Sigma)$  and  $c_2 = \max \gamma^{-1}(\Sigma)$ , both of which lie in (0,1) since  $p_1, p_2 \notin \Sigma$ . Hence

$$\gamma(c_1) \in \Sigma \cap V \quad \text{and} \quad \gamma(c_2) \in \Sigma \cap V$$
(77)

but also

$$\gamma([0, c_1)) \subseteq U_1 \quad \text{and} \quad \gamma((c_2, 1]) \subseteq U_2.$$
 (78)

Hence there exist  $t_1 \in [0, c_1)$  and  $t_2 \in (c_2, 1]$  s.t.

$$\gamma(t_1) \subseteq U_1 \cap V \quad \text{and} \quad \gamma(t_2) \subseteq U_2 \cap V.$$
 (79)

showing that p is indeed a boundary point of  $U_1$  and also of  $U_2$ . In order to see that all boundary points of  $U_1$  have to be contained in  $\Sigma$ , note that since  $\mathbb{R}^n \setminus \Sigma$  is an open subset of  $\mathbb{R}^n$ , all of its connected components are open. Hence for any  $p \in U_2$  there is a neighborhood V of p, which is disjoint from  $U_1$ . The same argument holds for  $U_2$ .

**Theorem 6.** Let  $A \subseteq \mathbb{R}^n$  be homeomorphic to the closed k-disk  $\mathbb{D}^k$  with  $k \leq n$ . Then  $\mathbb{R}^n \setminus A$  is connected.

*Proof.* Since A is homeomorphic to  $\mathbb{D}^k$ , it is compact and thus closed in  $\mathbb{R}^k \subset \mathbb{R}^n$ . Hence by corollary ?? the number of connected components of  $\mathbb{R}^n \setminus A$  coincides with that of  $\mathbb{R}^n \setminus \mathbb{D}^k$ , which is 1.

**Theorem 7.** (Brouwer) Let  $U \subseteq \mathbb{R}^n$  be open and let  $f: U \to \mathbb{R}^n$  be continuous and injective. Then  $f(U) \subseteq \mathbb{R}^n$  is open and  $f: U \to f(U)$  is a homeomorphism.

Proof. Since U is open in  $\mathbb{R}^n$ , it is a union of open balls B(r,x) around points  $x \in U$ . Hence, since images preserve unions, it is sufficient to show that the images f(B(r,x)) are open. Let r>0 and  $x \in U$  be arbitrary s.t.  $B(r,x) \subseteq U$  and write  $D:=\overline{B(r,x)}$ ,  $S:=\partial D$  and  $\dot{D}:=\operatorname{int}(D)=B(r,x)$ . Then since S is compact and  $\mathbb{R}^n$  is Hausdorff,  $\Sigma:=f(S)$  is homeomorphic to S, which is homeomorphic to  $S^{n-1}$ . Thus by theorem ??, the subspace  $\mathbb{R}^n \setminus \Sigma$  has two connected components,  $U_1$  (which is bounded) and  $U_2$  (which is unbounded); since  $\mathbb{R}^n \setminus \Sigma$  is open, so are  $U_1$  and  $U_2$ . By theorem ??, the subspace  $\mathbb{R}^n \setminus f(D)$  is connected, and since it is disjoint from  $\Sigma$ , it must be contained in either  $U_1$  or  $U_2$ . Since f(D) is compact, the subspace  $\mathbb{R}^n \setminus f(D)$  is unbounded and thus must be contained in  $U_2$ . Hence  $\Sigma \cup U_1 = \mathbb{R}^n \setminus U_1 \subseteq f(D)$ . Hence  $U_1 \subseteq f(\dot{D})$ . Since  $\dot{D}$  is connected and thus  $f(\dot{D})$  is also connected, and furthermore  $f(\dot{D}) \subseteq U_1 \cup U_2$  we conclude that  $f(\dot{D}) \subseteq U_1$  since otherwise  $U_1 \subseteq U_2$ . Thus  $U_1 = f(\dot{D})$ , which is open.

Let  $W \subseteq U$  be an open subset. Then by restricting f to W and applying the same argument as above we see that f(W) is also open. Hence f is a continuous, open bijection i.e. a homeomorphism.

**Corollary 3.** (Invariance of Domain) Let  $A \subseteq \mathbb{R}^n$  have the subspace topology induced by  $\mathbb{R}^n$  and be homeomorphic to an open subset U of  $\mathbb{R}^n$ . Then A is open in  $\mathbb{R}^n$ .

*Proof.* Follows by applying Theorem ?? to U.

**Corollary 4.** (Invariance of Dimension) Let  $U \subseteq \mathbb{R}^n$  and  $V \subseteq \mathbb{R}^m$  be non-empty open subsets. If U and V are homeomorphic, then n = m.

*Proof.* Assume that m < n and consider V as a (not necessarily open) subset of  $\mathbb{R}^n$  via  $V \subseteq \mathbb{R}^m \subseteq \mathbb{R}^n$  and topology induced by  $\mathbb{R}^n$  (or equivalently  $\mathbb{R}^m$ ). Since V is homeomorphic to U by assumption, corollary ?? implies that V is open an open subset of  $\mathbb{R}^n$ . This is a contradiction since V is contained in a proper linear subspace of  $\mathbb{R}^n$ .
